

FbSQL language specification — the fixed part

signatures · formula semantics (R's glm) · model relation columns · metadata schema · error policies
defined independently of any engine

PostgreSQL extension — reference implementation

one realization; engines are replaceable (C · GPU · distributed)

fit_glm()

PL/R → stats::glm()

R as internal engine
(never exposed to the user)

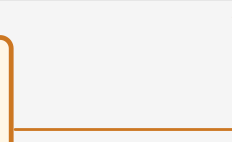

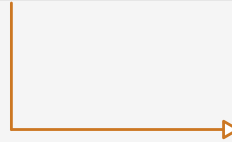

predict_glm()

PL/pgSQL — no R

computes from the model
relation alone

Model relation

term rows + metadata
*the boundary artifact:
all that crosses the engines*

Verification — conformance enforced continuously

pg_regress conformance suite · R parity at 4 decimals · pinned Docker environment · CI on every commit
any replacement engine must pass the same suite
